21 Running title: the effect of a 22-Month speaking-up programme

## 22 Abstract

### 23 Background

24 Speaking-up is a method of assertive communication, which increases patient safety, but of-  
25 ten encounters barriers. Numerous studies describe programmes introducing speaking-up  
26 with varying success; the common denominator seems to be the need for a multimodal and  
27 sustained approach in order to achieve the required change in behaviour and culture for  
28 safer healthcare.

### 29 Methods

30 Before implementing a 22-month multistep programme for establishing and strengthening  
31 speaking-up at our institution, we assessed perceived safety culture using the “Safety Atti-  
32 tudes Questionnaire”. After programme completion, participants completed parts of the  
33 same “Safety Attitudes Questionnaire” relevant to speaking-up, and pre- and post-results  
34 were compared. Additionally, levels of speaking-up and assertive communication were com-  
35 pared with a Swiss benchmark using results from the “Speaking-up About Patient Safety  
36 Questionnaire”.

### 37 Results

38 “Safety Attitudes Questionnaire” scores were significantly higher after programme comple-  
39 tion in two of three answered questions (5.0 (4.0, 5.0) versus 4.0 (4.0, 5.0)  $p=0.0002$  and 5.0  
40 (4.0, 5.0) versus 4.0 (4.0, 4.0)  $p=0.002$ , Median (1st quartile, 3rd quartile)) (n = 34). Our com-  
41 posite score on the “Speaking-Up About Patient Safety Questionnaire” was significantly  
42 higher ( $5.9 \pm 0.7$  versus  $5.2 \pm 1.0$ , mean  $\pm$  standard deviation,  $p < 0.001$ ) than the benchmark  
43 (n = 65).

44 **Conclusion**

45 A long-term multimodal programme for speaking-up was successfully implemented. Attitude  
46 and climate towards safety generally improved and post-programme perceived levels of as-  
47 sertive communication and speaking-up were higher than the benchmark. These results sup-  
48 port current opinion that multimodal programmes and continued effort are required, but  
49 that speaking-up can indeed be strengthened.

51 Speaking-Up, psychological safety, high-fidelity simulation, online learning

## 52 Introduction

53 Speaking-up is a method of assertive communication by which concerns, such as threats to  
54 patient safety or the presence of unsafe conditions, are stated with persistence until there is  
55 a clear resolution.<sup>1, 2, 3</sup> According to the Joint Commission's sentinel event data from 2015,  
56 the failure to speak up was one of the top three root causes for adverse events in the peri-  
57 operative period.<sup>4</sup> Withholding voice despite safety concerns is a common behaviour among  
58 health care professionals. A Swiss multicentre study reported that 19%–39% of health-care  
59 workers had chosen to withhold voice within the past four weeks.<sup>5</sup> Several barriers for  
60 speaking-up have been identified in the perioperative setting, including perceived ineffec-  
61 tiveness, presence of patients and authority gradients.<sup>1, 6</sup>

62 Research on the implementation of speaking-up has mainly focused on single groups, includ-  
63 ing nursing students,<sup>7</sup> medical students,<sup>8</sup> and residents.<sup>9, 10</sup> In general, implementation of  
64 speaking-up has demonstrated varying success,<sup>11, 12</sup> but common themes include: necessity  
65 for an implementation programme involving all members of staff, education to support a  
66 transformation in organisational culture,<sup>13</sup> and addressing norms and communication behav-  
67 iours.<sup>14</sup> In short, strengthening a culture of speaking-up is an ongoing challenge<sup>15</sup> but also  
68 crucial to increasing patient safety.

69 In order to establish and strengthen speaking-up in our department, we developed and em-  
70 ployed a 22-month multi-step implementation programme. To measure the effect of the  
71 programme, we compared perceptions of speaking-up before and after the intervention us-  
72 ing elements from the "Safety Attitudes Questionnaire", a validated questionnaire for per-  
73 ceptions of patient safety related attitudes, as our primary outcome. As a further measurement,

74 and secondary outcome, we compared post-intervention levels of speaking-up and assertive  
75 communication with comparable Swiss institutions using the “Speaking-Up About Patient  
76 Safety Questionnaire”.

## 77 **Methods:**

### 78 **Study institution and population:**

79 The study was performed in the Cantonal Hospital of Baden, a 382 bed teaching hospital of  
80 Zurich University, which annually treats more than 20`000 inpatients and more than 170`000  
81 outpatients. All staff members of the department of anaesthesia, i.e. nurse and physician  
82 anaesthetists (both residents and consultants) employed at any time during the 22 months  
83 were exposed to the implementation programme. The requirement for approval of our  
84 study, as well as for written consent, was waived by the ethical committee “Nordwest-  
85 schweiz” as well as by our institutional legal board. Participants gave verbal consent. Mate-  
86 rial was de-identified before any analysis, and destroyed hereafter in conformance with legal  
87 requirements.

88 A total of 117 staff members participated in the implementation programme at some time  
89 during the 22 months, but due to staff fluctuations, availability, and study requirements, the  
90 number of available participants varied over time. Details are presented on the timeline of  
91 the project in Figure 1.

92

93 Fig. 1: the implementation programme – of 177 members of staff present at some time during the in-  
 94 tervention, 57 participated in the baseline survey, of which 34 completed the repeat survey, providing  
 95 data for the primary objective. Independent of participation in the baseline survey, 65 members of  
 96 staff completed the programme and were available for the Speaking-Up About Patient Safety survey,  
 97 the secondary outcome.

## 98 Baseline survey

99 Prior to implementing the programme, the 57 current members of staff available completed  
 100 the German language version of the Safety Attitudes Questionnaire. This questionnaire is a  
 101 validated tool to assess<sup>16, 17</sup> healthcare workers' perceptions of patient safety related atti-  
 102 tudes in various clinical areas. Depending on the version, it is comprised of 30 – 60 items  
 103 measured on a 5-point Likert scale covering six aspects of the safety climate: teamwork cli-  
 104 mate, job satisfaction, safety climate including perception of speaking-up, stress recognition,  
 105 working condition and perception of management. The German translation was recently val-  
 106 idated<sup>18</sup> and successfully tested in 10 Swiss hospitals<sup>19</sup> and transcribed to the Survey Mon-  
 107 key © online platform for our survey of baseline values.

108 The Implementation Programme

109 Following the baseline survey, the multimodal implementation program was initiated in Au-  
110 gust 2019, and incorporated into the entire anaesthesia department over a course of 22  
111 Months. It consisted of various elements including an awareness campaign, an on-line  
112 course, simulation based team trainings, and explicit invitation to speak-up incorporated  
113 into daily practice.

114 To begin the programme, all current staff members were required to participate in the  
115 online course developed using the hospital's native e-learning software, © easylearn  
116 schweiz ag, comprised of three components. Firstly, background knowledge and the ra-  
117 tionale for speaking-up were presented together with instructions including the two-chal-  
118 lenge rule,<sup>20</sup> and providing coaching in advocacy-inquiry with specific examples. The second  
119 element was a video featuring the department head as the recipient of speaking-up. Finally,  
120 there was a multiple choice exam testing participant's knowledge on rationale and barriers  
121 for speaking-up, the effect of the authority gradient, and identification of the correct word-  
122 ing of speaking-up using crisp advocacy-inquiry in various described situations. This exam  
123 was graded, and a pass was required. One year later, members of staff were again exposed  
124 to the same mandatory online course module as a refresher.

125 Complementing the teaching, we performed three high-fidelity in-situ simulations with vari-  
126 ations of opportunity for speaking-up throughout the implementation programme, to which  
127 we assigned as many staff members as rostering allowed during the pandemic:

128 • interdisciplinary team-training for obstetric anaesthesia staff with scripted opportunity  
129 for speaking-up during the scenarios (40 participants from our department) in December  
130 2019

131 • anaesthesia induction sequence with scripted speaking-up situations with an acting in-  
132 structor (75 participants) in October 2020,

133 • interdisciplinary team-training sessions for same-day surgery teams, and obstetric anaes-  
134 thesia teams, with special focus on speaking-up in debriefings (29 participants from our  
135 department) in April 2021

136 Scenarios and teaching elements were developed and tested prior to study-use by the Au-  
137 thor C.S., a trained instructor for medical simulation with experience developing standard-  
138 ised scenarios for measurement and research,<sup>21</sup> then refined by the authors C.S., F.W. and  
139 M.H. using a modified Delphi approach, and finally tested by fellow simulation instructors.

140 Additionally, the programme was accompanied by a continuous awareness campaign includ-  
141 ing various lectures and workshops reiterating the topics of the online course (background  
142 knowledge and the rationale for speaking-up, instructions and suggestions for providing  
143 speaking-up, and coaching in advocacy-inquiry with specific examples), and an interview  
144 with the head of the department in the hospital newspaper, in which he discussed hierarchy  
145 and status issues, introduced the concept of, and called for, speaking-up.

146 Finally, as of January 2020, we incorporated speaking-up into our daily clinical practice by  
147 augmenting the pre-induction checklist and team-briefing with the request to perform  
148 speaking-up made by the highest-ranked team member. This action served a dual purpose –

149 as an ongoing reminder of leadership commitment to speaking-up, and a tool to reduce the  
150 barriers of hierarchy by the mechanism of leader inclusiveness – words and deeds by leaders  
151 that invite and appreciate others’ contributions which can take nature off its course, helping  
152 to overcome status’ inhibiting effects on psychological safety.<sup>22</sup>

### 153 Primary Outcome – Pre-Post comparison using the “Safety Attitudes Questionnaire”

154 For our primary outcome, we interviewed all current members of staff who completed the  
155 whole implementation programme and had participated in the baseline survey (n = 34) using  
156 the following three questions from the “Safety Attitudes Questionnaire” used for the base-  
157 line survey, which specifically focus on assertive communication and speaking-up, after the  
158 implementation period of 22 months and compared scores:

- 159 • *In this clinical area, it is difficult to speak up if I perceive a problem with patient care.*
- 160 • *In this clinical area, it is difficult to discuss errors.*
- 161 • *I am encouraged by my colleagues to report any patient safety concerns I may have.*

162 Both cohorts contained the same participants and results were compared unpaired.

### 163 Secondary Outcome – comparison of results from our institution with the benchmark of 164 comparable Swiss institutions using the “Speaking-Up About Patient Safety Questionnaire”.<sup>23</sup>

165 65 members of staff participating in the implementation programme from the beginning and  
166 available at the time of the survey completed the Speaking-Up about Patient Safety Ques-  
167 tionnaire, a validated questionnaire developed by the Swiss Patient Safety Foundation focus-

168 sing on speaking-up and assertive behaviour among healthcare staff. Specifically, the ques-  
169 tionnaire assesses the two theoretical constructs of speaking-up and withholding voice,  
170 while covering three speaking-up climate related subscales: psychological safety for speak-  
171 ing-up, encouraging environment, and resignation. The Questionnaire has been used in 22  
172 Swiss hospitals, and in 5 comparable departments, which allows valuable cross-hospital  
173 comparisons of speaking-up behaviours and climate.

#### 174 [Statistical analysis](#)

175 Results for the primary and the secondary outcome were examined by inspection of the his-  
176 tograms. Negatively worded items were reversed before statistics were performed. Two-  
177 sided p-values < 0.05 were considered statistically significant. All statistical analyses were  
178 conducted using R version 4.0.2<sup>24</sup>

179 To compare the pre- and post-implementation results of the three relevant questions on the  
180 Safety Attitudes Questionnaire (1<sup>o</sup> outcome), a Mann-Whitney U-Test for non-paired sam-  
181 ples was performed. Due to the small sample size and lack of normal distribution, we pre-  
182 sent the median, and 1<sup>st</sup> and 3<sup>rd</sup> quartile.

183 Concerning the secondary outcome, we compared the results of the “Speaking-Up About Pa-  
184 tient Safety Questionnaire” to the benchmark values using Welch's t-test for unequal vari-  
185 ances; here, we report the mean and SD according to previous analyses.<sup>23</sup>

186 **Results**

187 **Primary outcome**

188 Of the 57 members of staff initially completing the pre-implementation Safety Attitudes  
189 Questionnaire, 34 (59.6%) completed the whole implementation programme and were also  
190 available for the post-implementation survey with the three relevant questions from the  
191 questionnaire.

192 Scores after implementation were significantly higher in 2 of 3 questions surveyed and did  
193 not change significantly in the third question (Table 1).

| Safety Attitudes Questionnaire (measures on a 6-point scale)<br>(n=34)                                     | Median (1 <sup>st</sup> quartile, 3 <sup>rd</sup> quartile) |                     | p value <sup>2</sup> |
|--|---|---------------------|----------------------|
|  | pre-implementation  | post-implementation |                      |
| In this clinical area, it is difficult to speak up if I perceive a problem with patient care. <sup>1</sup> | 4.0 (4.0, 4.75)   | 5.0 (4.0, 5.0)      | 0.0002               |
| In this clinical area, it is difficult to discuss errors. <sup>1</sup>                                     | 4.0 (4.0, 4.0)  | 5.0 (4.0, 5.0)      | 0.0022               |
| I am encouraged by my colleagues to report any patient safety concerns I may have.                         | 4.0 (3.0, 4.0)  | 4.0 (3.0, 5.0)      | 0.7220               |

<sup>1</sup> negatively worded items are reverse coded for the total score.  
<sup>2</sup> p-values: Mann-Whitney U-Test for non-paired samples

195 Table 1: comparison of median (1<sup>st</sup> Q, 3<sup>rd</sup> Q) responses to Safety Attitude Questionnaire items pre- and  
 196 post-implementation.

### 197 Secondary outcome

198 A total of 65 members of staff which had completed the implementation programme also  
 199 completed the Speaking-Up About Patient Safety Questionnaire. Safety concerns were com-  
 200 mon among survey participants. The majority reported at least one patient safety concern  
 201 during the past four weeks (92%). At least one episode of speaking-up during the past four  
 202 weeks was reported by 94%. At least one episode of “withholding voice” was reported by  
 203 58%. The barriers reported by respondents as hindering them to voice their concerns were  
 204 reaction of the actor not predictable (35%), presence of patients or relatives (34%), ineffec-  
 205 tiveness of speaking-up (31%), unclear risk for the patient (29%), difficulty finding the right  
 206 tone (12%) and fear of negative reactions (8%).

207 Overall responses to the climate survey items are reported in Table 2. Results obtained in  
 208 this study were higher when compared to the Swiss perioperative care sample.<sup>6</sup> Respon-  
 209 dants in our hospital reported higher levels of psychological safety, a more positive encour-  
 210 aging environment, and described less resignation towards speaking-up.

| Items and scales (measure on a 7-point Likert scale)  | Mean (SD)          |   | p value <sup>2</sup> |
|---|--------------------|---|----------------------|
|   | This sample (n=65) | Swiss perioperative care sample (n=360) |                      |
| <i>Psychological Safety for Speaking up, mean scale score</i>   | 6.2 (0.6)          | 5.5 (1.1)                               | <0.001               |
| I can rely on my colleagues (doctors and/or nurses), whenever I encounter difficulties in my work.                        | 6.4 (0.6)          | 5.6 (1.4)                               | <0.001               |
| I can rely on the shift supervisor (person in charge of a shift) whenever I encounter difficulties in my work.            | 6.4 (0.9)          | 5.6 (1.6)                               | <0.001               |
| The culture in my unit/clinical area makes it easy to speak up about patient safety concerns.                             | 6.2 (0.9)          | 5.4 (1.6)                               | <0.001               |
| My colleagues (doctors and/or nurses) react appropriately, when I speak up about my concerns about patient safety.        | 5.9 (0.9)          | 5.4 (1.2)                               | <0.001               |
| My shift supervisors (person in charge of a shift) react appropriately, when I speak up about my patient safety concerns. | 5.9 (1.0)          | 5.5 (1.4)                               | 0.009                |
| <i>Encouraging Environment for Speaking up, mean scale score</i>  | 5.9 (0.9)          | 4.9 (1.4)                               | <0.001               |
| In my unit/ clinical area, I observe others speaking up about their patient safety concerns.                              | 5.6 (1.2)          | 5.2 (1.5)                               | 0.028                |
| I am encouraged by my colleagues (doctors and/or nurses) to speak up about patient safety concerns.                       | 6.0 (1.1)          | 4.6 (1.7)                               | <0.001               |
| I am encouraged by my shift supervisor (person in charge during a shift) to speak up about patient safety concerns.       | 6.1 (1.1)          | 4.9 (1.8)                               | <0.001               |
| <i>Resignation towards Speaking up, mean scale score</i>  | 2.5 (1.1)          | 3.2 (1.4)                               | <0.001               |
| When I have patient safety concerns it is difficult to bring them up. <sup>1</sup>  | 2.0 (1.1)          | 2.4 (1.6)                               | 0.002                |
| Having to remind staff of the same safety rules again and again is frustrating. <sup>1</sup>                              | 3.1 (1.7)          | 3.9 (2.1)                               | <0.001               |
| Sometimes I become discouraged because nothing changes after expressing my patient safety concerns. <sup>1</sup>          | 2.5 (1.5)          | 3.1 (1.9)                               | 0.004                |
| <i>Total speak up climate score (mean across items)</i>   | 5.9 (0.7)          | 5.2 (1.0)                               | <0.001               |

<sup>1</sup> negatively worded items are reverse coded for the total score.  
<sup>2</sup> p-values: Welch's t-test for unequal variances

212 Table 2: comparison of mean (SD) responses to climate survey items for our department and the Swiss  
213 comparison.

## 214 Discussion

### 215 Results

216 We found that the 22 month implementation programme was associated with higher levels  
217 of self-reported speaking-up behaviour, as evidenced by a significant improvement in two of  
218 three elements on the post-implementation Safety Attitudes Questionnaire items addressing  
219 assertive communication and speaking-up, and higher over-all scores in the climate survey  
220 as compared to the benchmark of similar healthcare institutions in Switzerland.

221 Although our study did not investigate the effects of each separate intervention within the  
222 programme, evidence does suggest that leader inclusiveness and leadership support is criti-  
223 cal – as such, we feel that our head of department providing interviews, lectures, and a  
224 scripted video inviting to speaking-up was essential for the programme’s success and pa-  
225 tient-safety climate in our department.

226 Although there was an improvement in 2 out of 3 responses on the Safety Attitudes Ques-  
227 tionnaire, the survey question “I am encouraged by my colleagues to report any patient  
228 safety concerns I may have” did not show any improvement post implementation. We be-  
229 lieve this might be because of the relatively high baseline value (4.0 on a 5-point scale), and  
230 the fact that our implementation programme did not explicitly focus on peer support as  
231 much as the more prominent issues of hierarchy, leadership and empowerment. Also, the  
232 request to perform speaking-up expressed by the highest ranked team member at every in-  
233 duction might have made encouragement by other team members seem less important.  
234 However, this evidence seems to show that strengthening of peer support to do the right  
235 thing might indeed need more focus in consecutive programmes.

236 Although the higher over-all scores in the Speaking-up About Patient Safety Questionnaire as  
237 compared to the benchmark of similar healthcare institutions in Switzerland suggest a posi-  
238 tive effect of our implementation programme, some results are sobering, albeit not unex-  
239 pected. Although most respondents reported at least one patient safety concern during the  
240 past four weeks, over half reported withholding voice within the same period - this is a stark  
241 reminder of the fact that even an intervention of our dimension is only one step on the road  
242 to patient safety. Reported barriers (unpredictable reaction of recipient of speaking-up,

243 presence of patients or relatives, assumed or experienced ineffectiveness of speaking-up, an  
244 unclear risk for the patient, difficulty finding the right tone and fear of negative reactions)  
245 persist, and provide a road map for further interventions. As we only implemented our pro-  
246 gramme in the department of anaesthesia, we must consider one barrier, the assumed or  
247 experienced ineffectiveness, in context of interdisciplinary communication in particular: if  
248 the culture of patient safety and leadership support for speaking-up is less well established  
249 in a department closely interconnected such as surgery, there is a limit to the benefit for pa-  
250 tient safety which can be achieved by improvements in one department only.

251 **Strengths of our study:**

252 To our knowledge, our study is one of the first to detail a longitudinal and multifaceted im-  
253 plementation programme involving all levels of staff and leadership, addressing speaking-up  
254 and voice behaviour, and providing objective measures of its success. A further advantage is  
255 our comparison of scores to a national benchmark.

256 **Limitations of our study:**

257 Our study is limited by its small size and relatively small response rate. Due to the require-  
258 ment that study participants completed the whole implementation programme and staff  
259 fluctuation over the 22 months, overall numbers were smaller than expected. Additionally,  
260 the prominence of leadership support in “safe behaviour” makes a Hawthorne effect highly  
261 likely.

262 Furthermore, at the time of the study we did not have a structured reporting instrument for  
263 near misses and adverse events in place apart from the critical incident reporting system,

264 which due to legal restrictions in Switzerland cannot be considered a representative data-  
265 base. Improvements in reporting are a logical next step for the implementation programme.

266 Another possible limitation is that this study was a single centre study in one department  
267 and cultural region; it is unclear in how far results are reproducible in another department,  
268 institution, or even country with different norms and cultures. Indeed, a department of an-  
269 aesthesia with a traditionally shallow hierarchy in Switzerland (being a country with low  
270 power distance index but relatively high scores on indices for individualism, masculinity, and  
271 uncertainty-avoidance according to Hofstede's cultural dimensions) probably requires em-  
272 phasis on different elements of a multimodal approach as would a different department or  
273 population in another cultural setting. Due to this limitation, we feel that a rigorous investi-  
274 gation into perceived barriers before implementing such a program – as we performed using  
275 the Safety Attitudes Questionnaire – can provide valuable guidance to address these differ-  
276 ences.

## 277 Conclusion

278 A long term, inclusive and multi-step programme for establishing speaking-up was success-  
279 fully implemented at our institution. Attitude and climate towards safety in our department  
280 improved after implementation according to “SAQ”-scores; the “Speaking-Up About Patient  
281 Safety Questionnaire” respondents at our institution reported higher levels of psychological  
282 safety, a more positive encouraging environment, and described less resignation towards  
283 speaking-up, as in comparable Swiss institutions. These results seem to support current  
284 opinion that, although a multimodal programme and continued effort are required to assist

285 the change in culture and behaviour towards safer healthcare, increases in levels of speak-  
286 ing-up can indeed be achieved.
